Is there a way within ENVI for a user written function to get data from a plot window? I'd like for a user to be able to create a Z-profile plot, after figuring out which pixel he wants to analyze. Then, he'd look at the plot and figure out which Z-values to analyze further. The zoom feature on the plot window works nicely for this. Then, I'd like for the data selected in the zoomed version of the plot window to be passed to a function that I'll write in IDL to do some custom analysis. Is there any way for a user function to get the data displayed in a Z-plot? The output data to ASCII seems to always use the entire Z range regardless of zooming in the window. Of course I really just need the X, Y locations and the Z range selected and then I can extract the data, but I can't find any documentation about how to communicate with the plot window at all.

Thanks for any help.
