
Subject: working with restored values

I am restoring a large save file, and displaying some of the variable names to the user to choose from in a droplist.

```
restore, 'junk.sav'  
help, output=tmpstr  
varlist = strarr(5)  
varlist = tmpstr(0:4)  
widget_control, droplist, set_value=varlist
```

i would like to save the actual values of the variables in a pointer array or structure. (have this be the uvalue of the droplist?)
but how would i do this?

later i would be using the pointer array or structure in the event loop of the droplist to do calculations with the value chosen.

cathy
