<BLOCKQUOTE TYPE=CITE>Hi:

<P> I'd like to program the following routine: giving two set of vectors with n and

m vectors respectively (a matrix of size pxn and another of size pxm),

I want to

obtain a matrix of size nxm where the element (i,j) is the euclidean distance

from first set's vector i to second set's vector j. I know the solution using

loops, but exists it a different way without loops?</BLOCKQUOTE>

Here's my (quick and dirty) solution for two vectors.

```
<P>&nbsp;&nbsp;&nbsp; function edist, a, b
<BR>&nbsp;&nbsp;&nbsp; na = n_elements( a )
<BR>&nbsp;&nbsp;&nbsp; nb = n_elements( b )
<BR>&nbsp;&nbsp;&nbsp; ; print, na, nb
<BR>&nbsp;&nbsp;&nbsp; aa = a
<BR>&nbsp;&nbsp;&nbsp; bb = b
<BR>&nbsp;&nbsp;&nbsp; aa[*] = 1
<BR>&nbsp;&nbsp;&nbsp; bb[*] = 1
<BR>&nbsp;&nbsp;&nbsp; c1 = a^2#bb
<BR>&nbsp;&nbsp;&nbsp; c2 = aa#b^2
<BR>&nbsp;&nbsp;&nbsp; c = c1+c2
<BR>&nbsp;&nbsp;&nbsp; c = sqrt(c)
<BR>&nbsp;&nbsp;&nbsp; ;Check with loops
<BR>&nbsp;&nbsp;&nbsp; ;d=dblarr(na,nb)
<BR>&nbsp;&nbsp;&nbsp; ;for k=0,nb-1 do begin
<BR>&nbsp;&nbsp;&nbsp; ;for j=0,na-1 do begin
<BR>&nbsp;&nbsp;&nbsp; ; d[j,k]=sqrt(a[j]^2 + b[k]^2)
<BR>&nbsp;&nbsp;&nbsp; ;endfor
<BR>&nbsp;&nbsp;&nbsp; ;endfor
<BR>&nbsp;&nbsp;&nbsp; ;print,' '
<BR>&nbsp;&nbsp;&nbsp; ;print,c-d
<BR>&nbsp;&nbsp;&nbsp; ;return, c
<BR>&nbsp;&nbsp;&nbsp; end
```

<P>You can easily generalize to matrices by inserting code, before

the second line, that checks dimensions of a and b, and transforming

a and/or b to one-dimensional array via reform function.
