Hi all!

We are running IDL 5.1 on Digital UNIX and accessing it from different platforms with various X Servers (MacX on the Mac, Exceed on Windows (NT/Alpha)), and have run across an odd problem with color.

Off of the Mac and off of the host itself, everything works fine...color is great, yadda yadda yadda. Off of the Alphas running Exceed, using tv or tvscl to display an image does not display color (although using plot with the color keyword DOES display color). Fine, I thought, just a problem with Exceed, or with how Exceed is set up. Well, it turns out that if we run "demo" first, and THEN our program, everything works fine and color comes out nicely. Running demo does give us an error message with text similar to "Unsupported XWindows Visual (class: Psuedo_color, depth=8)" and "Substituting default visual (class: true_color)" (I did this from memory, so if it's not entirely accurate, don't worry. =) So we tried using

device, true_color=24

and that didn't work...still no color using tvscl or tv. So at this point, I'm rather stumped. I was hoping someone in this group (since you've all been so helpful to other lost souls in the past) might have a suggestion or even better, an answer.

Thanks in advance for any info! Please e-mail a copy if that is convenient.
