Subject: handling of different(many) processes

Hi,

I like to have a mechanism which allows me to put some routines into a
idl background proccess while an other process is running.

I believe this is possible with widgets.

But what did I have to do with normal routines like:

reading 30 MB into a structure
calculating something

while saving to a sav file returning to the user.

or returning to the user while saving to a sav file.

At the moment I have to save to a sav file and after it's finished I am
able to return.

Any ideas are welcome!
