Folks,

I spoke a bit too soon the other day in a reply to Liam about 24-bit color displays. As it happens, that annoying little bug in which 24-bit images are routed through the color tables if color decomposition is OFF is still with us in IDL 5.2.1.

This means that to display a 24-bit image properly on a PC you must either have the gray scale color table loaded (colortable 0), or you must have color decomposition ON (Device, Decomposed=1).

It is a gigantic inconvenience to have to check for this each and every time you display an image, but short of using my TVIMAGE program (which *\*does\** check), that's about the size of it. Of course, you only have to check on PCs, so that will cut your checking at least in half, I guess. :-)

Anyway, I already have my IDL 5.3 beta bug report filled out. I'm just waiting for the darn software to arrive so I can send it in. :-)

Cheers,

David
