You should have a look at

_REF_EXTRA: Passing Keyword Parameters by Reference

You can pass keyword parameters to called routines by reference by adding the formal keyword parameter "_REF_EXTRA" (note the underscore character) to the definition of your routine. Passing parameters by reference means that you are giving the called routine the name of an existing IDL variable to work with; IDL takes care of keeping track of the value associated with the name. The values of keyword parameters specified via _REF_EXTRA are not available to the routine that is passing the keywords on.

When a routine is defined with the formal keyword parameter _REF_EXTRA, pairs of unrecognized keywords and values are placed in a storage location that is

accessible to both calling and called routines, and the keyword names are placed in an IDL string array. The string array can be "deciphered" using the `_EXTRA` keyword, which matches the names in the string with the "live" values in the storage location. This means that if the keywords specify IDL variables, the values of those variables can be altered by any routine that has access to the variable via the keyword inheritance mechanism. In this fashion, the values of keyword parameters can be changed within a routine and passed back to the routine's caller.

The "pass by reference" keyword inheritance mechanism is especially useful when writing object methods, which may be inherited multiple times and which often wish to change the value of variables available to the calling method. (The values of object properties are one example of data that can profitably be shared by objects at various levels in an object hierarchy.)

I am myself don't like common blocks. I prefer `_extra` and `_ref_extra` or heap variables

I hope that's common blocks will be obsolete in future. So everybody - RSI too will clean up those programs.
