Hi all,

I'm running IDL on a dual processor
Linux machine.

When I run two intensive IDL jobs so
that both processors are being used,
the machine freezes, and I have to reboot.
The machine will freeze with a matter of
seconds. TOP shows 100% usage at freeze point.

I can run multiple compiled C or FORTRAN
programs all day just fine.

RSI says that they cannot duplicate the problem.

Does anyone have any suggestions?
Is this a problem with IDL, REDHAT, motherboard???

I'm using REDHAT Linux 6.1
and IDL 5.3 or Linux.

The problem also occurred with RH 6.0
and IDL 5.2.

Thanks
