
Subject: Why do two graphics objects in the same program appear in two different windows?

I have a widget-based application which is a 3-D model of a Roche-lobe filling star, and I am trying to plot an array of points in the same window using the plot and oplot commands, but they appear in a separate window. I tried defining the array as an IDLgrImage, because the star is defined as a IDLgrModel, but it still plots in a separate window. Any idea on how to combine the two (the array is not part of the widget)
