I have a short question. When you have several (identical, object plotting only) widget windows, how do you find out which one is the topmost without using a common block or defining a main-level variable? I use focus events all right, but I have not figure out where to keep the resulting information.

I certainly will use a pointer if all those daughter windows are generated from a parent widget program. But how do I do this if I create them from a command line?

Thank you,

Pavel
