Hi experts:

I am stuck with a problem using a sav file:

My program is an widget driven i/o interface for FACSIMILE. It consists of about 400 functions/routines. When I compile the whole thing using `resolve_all` it works fine in this IDL session. However, when I save the thing (`easy.sav`) and restart IDL using the `easy.sav` file it worked fine for a while, then the thing crashes IDL totally during operation even when I use the same input data. Restarting IDL with sav file: crash. Restarting IDL with source compiled: OK. Save and restart: Crash. Rebooting and repeating gives the same result. I can also reproduce this behaviour on a different machine, with different user profile. I had the same behaviour with a previous version of the program which crashed in the same way at a different location in the program but I cannot reproduce this again :-|

Does anybody have similar problems? Is there any possibility to catch an error before IDL crashes?

I am using: { x86 Win32 Windows 5.3.1 Feb 23 2000 }

Best regards

Theo
