Sorry to bother everyone again. I am just beginning my enduring journey of learning IDL and keep running into obstacles.

My current problem is with printf. I am trying to create a text output file that can be imported into a spreadsheet. My problem is that printf is automatically line wrapping. For example:

```
printf, fileptr, val1, val2, val3, val4, val5, val6,
```

is producing output where val1, val2, val3, and val4 are on a single line. But, val5 and val6 are placed on the following line. NOTE: I am actually trying to print 10 different floats on the same line.

I did think about converting all the values into one long string and printing that string. But, this issue was still a problem.

Anyone have any ideas about how to fix this? Is a solution even possible?

Thanks,

Alan
