PV-WAVE is working on a debugger. It's still (I think) in beta test. It's basically just a tcl wrapper around a wave session, but it does a pretty good job of setting breakpoints (by clicking source code lines) and stuff like that. It does have some limitations, but most are no different than you get with the command line version.... I understand that there are more improvements in the works (like linking things more directly into the WAVE kernel).

You can pick up a copy on their ftp site, ftp://ftp.pvi.com/VNI/ (or something very much like that).
