This problem (getting the size of the screen without task bar, or in other terms, the size a maximized window should have) is not unique to Windows. It occurs in a very similar fashion in KDE (a widely-used graphical frontend to Linux). KDE has a task bar much like Windows, and a menu panel. Both can be placed at different positions on the screen, hidden etc. The K window manager knows how to determine the screen area usable for windows, but I do not know if IDL can find out. Anyway, GET\_SCREEN\_SIZE has the same limited functionality as in Windows.
