Subject: a simple question about strings

Hello.

I'm trying to format some data into one long line of various types of data.

My simple problem is that I am out of room to write the code on one line.

Normally, you can use the '\$' to continue your code on the next line.

However, this does not work inside strings. Is there an analogous character or magic combination of characters that does the same thing? If not, how can I format my ridiculously long and complex output?

Thanks in advance.
