I recently began to use IDL WIDGETS (on DEC ALPHA) and I have a minor problem: I created a base WIDGET with multiple editable text children to be used as an editable menu. I invoke the WIDGET and register it with XMANAGER, with the keyword JUST_REG. When I want control of the WIDGET, I type XMANAGER,widget_id. The problem is as follows: I want to be able to desensitize some of the children, so the user can only alter a single menu entry (I am running a complicated IDL code concurrently). I thought I could destroy the WIDGET and rebuild it with only one child sensitive. Is this possible, or is there a more appropriate method? Thanks -Bob
