Please, "Hey, Bro" is fine. :-)

Well, it might **seem** to operate this way, and
in fact there is no real harm **thinking** it operates
this way, but the facts are slightly more complicated.
In truth, it operates just like this:

```
IDL> a = reallybigdata  
IDL> a = reallylittledata
```

That is to say, pointers use IDL's normal ability
to allocate memory on the fly and change the type
and structure of IDL variables on a whim.

Where you are probably going wrong is thinking that
IDL pointers are anything at all like C pointers. They
are not. In fact, the only thing that is even remotely
similar about them is their name. :-)

Pointers in IDL are simply normal variables that exist in
a globally accessible area of memory that IDL itself
manages. Nothing more or less. The fact that they
are globally accessible gives them properties that
are useful to us. Namely, we can have multiple program
modules accessing large amounts of data just by carrying
around a light-weight token that you can easily think

of as a secret decoder ring. If you know the code, you can see the data. Simple as that.

In fact, if you know the code, you can change the data encrypted by the code. IDL itself will take care of all the messy details of how this is done. (CIA special ops, is what I hear.)

- > 1.. The Pointer is created - a variable that 'points' to space in RAM
- > reserved for a variable of indefinite size.

No, it actually points to a variable of a very defined size: the size of the variable it points to. If you don't know how big the data is going to be, or if you don't yet have a variable to store there, but you still want a valid pointer, you can make the pointer point to an "undefined" variable. Undefined variables are perfectly legitimate variables in IDL:

```
IDL> ptr = Ptr_New(/Allocate_Heap)
IDL> HELP, *ptr
<PtrHeapVar110> UNDEFINED = <Undefined>
IDL> Print, Ptr_Valid(Ptr)
1
```

- > 2.. The data is read into RAM during the read_image.pro.

Yes.

- > 3.. The Pointer then needs to store the image data for future reference.
- > This is done by '*info.image = newimage'. Where newimage is the image data
- > in RAM.

Yes,

```
IDL> *ptr = newimage
```

Now the pointer points to a defined variable that is a defined size. IDL itself has managed all the memory allocation, etc. for you.

- > 4.. Is the data then copied into the space originally allocated for it or
- > does it simply change it's reference so as to point to the location in RAM
- > where the image data was read into?

Uh, I don't know. And frankly, I don't even want to know. It's fast, so I suspect the image data itself doesn't move. I prefer to think of it being done with smoke and mirrors,

since it seems more mysterious that way. The point is, even if you knew how it was done there is nothing you can do in your code to affect how it is done, so there really is no point in worrying about it.

Don't ever review anything in C or C++ if you want to know about IDL. It will just confuse the daylights out of you. :-)

Cheers,

David
