We have a number of procedures written which display our data. One user runs wave on a Decstation and displays on his Sun Sparc. One of the many displays causes his workstation to crash hard (reboot only way out). I believe it is a plot with symbol. This display worked at one time on his workstation. It has crashed other Suns but not consistently. The graphics board has been replaced. The wave client reports a loss of connection timeout which is consistent with the crash we see on the sun end.

Question: 1) Anybody seen anything like this?

2) Anybody have any ideas on what type of information could be gathered to solve this problem?

We are using wave 3.1 and the Sun manager claims he is using the latest...

bryan
