Hey there,

I've had this process running for about, oh, 4-5 hours now where I'm reducing the resolution of an input spectrum of about 500K points (i.e. a lot, but not terribly so.). Earlier I did the same for a spectrum of about 700K points. Something has apparently gone haywire in the second one - is there anything I can do to interrupt the process, check out some numbers to see if everything is o.k. and if it is, start it up where it left off? I think that's what a ^C does but I thought I better consult the idl wizards out there...

thanks for any info.

paulv
