From your previous code, I assume you meant:

```
max308=max(data(3,*), maxindex)
```

```
max353=max(data(5,*), maxindex)
```

but what if the maximum value for the different columns of data occurs at a different index? Shouldn't you do something like,

```
max308=max(data(3,*), max308index)
```

```
max353=max(data(5,*), max353index)
```

??

If not, why bother with returning maxindex for data(3,\*)?

me confuzzed.
