 I think this is the key. If I were ever to put together a library
of routines suitable for public use (oink oink, flap, flap) the most
natural way seems to create a package object and make all the routines
methods. There is no law that says an object's methods have to act on
its internal data. Converting existing libraries and the code that uses
it could probably even be automated.

 Xwindow gets my vote for the highest combination of usefulness and
namespace conflicts (you know who you are....).
