I am trying to create a table widget that displays read-in data into
two columns using "use_table_select" and "set_value" commands. The
problem is I can read in the first column of data no problem but the
second column of data only reads in one element of data in the second
column or not at all.

I have tried reading the data into an array, into structures and
creating a vector of structures all to no avail. Are there any
seasoned idl programmers able to help a newbie in distress???

Ben
