Hi.

Sometimes I want use keyword variables (or parameters) of a function or procedure in routines not only in the main program (of the function/procedure) but also on subroutines (as often happens with routine events). Intuitively I put the keyword variables on a block shared with the subroutine that I also want to use those variables. But it gives an error; that I can't remember now. It forces me to create new variables where I put the contents of the keyword variables, and then those variables I created in the program I can share with subroutines with common block.

Is there a way that I can achieve this without making as many attributions as many keyword variables I want to share in COMMON blocks?
