
Subject: Need help with value_locate and interpolation

I'm having some trouble with using the value_locate function. Let's say I have a vector with 10 elements, and I want to find the "interpolated" array index for a particular value. I know how to interpolate the vector, but I can't find a way to return the index as a float and not an integer. In other words, given a certain value of the array, I would like to find a way to return the information that that interpolated value is at an index of, say, 4.27. Is there a simple way to do this?

Thanks,

Leslie
