I've ported some FORTRAN code to SUN, and successfully created the FORTRAN shareable object for IDL's call external. The application worked great.

Next, I tried SOLARIS V3.3, and I get an error on a FORTRAN READ statement (which worked fine on SUN). At the statement

```
READ (5, 8020, ERR=8030, END=8888) INPUT
```

the program does not wait for my string input. Upon printing INPUT, I see that the program believes it is a null string, although I haven't entered anything. I tried other combinations: changed 5 to \*, removed the branches ERR=, END= ...still the same results. Does anyone have a clue?

Thanks

PS The FORTRAN was originally written for VMS, but the READ does not use any of the VAX FORTRAN extensions...
