Hi,

We have had a number of requests from our software users to be able to save the "state" of the GUI application prior to closing it so that users can restore it at a later time. The GUI applications are typically written as object widgets that can contain many other objects. The relationship with the the GUI and other objects can be has-a and is-a. I know that there are certain tricks related to saving objects and restoring them (as discussed on this NG) but I don't have that much experience doing this myself. I am probably asking too much but....is there a straightforward way to modify existing object widgets that allows the user to save and restore the widget state?

Many thanks in advance,

Rob
