We have used Callable and the JNI to create a small native Java object that wraps IDL's (Callable) Execute String method. The one catch is that no array data is passed. Strings and scalar args are fine, as are behavioral keywords, but reorganizing array layouts from Java to IDL is not easily handled in a general sense and went far beyond what I needed at the time.

This Callable/JNI wrapper was built for a prospect who simply needed to call an IDL .sav file that took a string for an arg (filename). IDL did some processing and then wrote the result out to 'filename' on disk (NOTE: No array data passing and will not run under IDL's Virtual Machine).

Remember too that ION (IDL On the Net) would work for you (and you can pass data as well as display IDL graphics in a native Java Canvas). It's based on a client/server model which is primarily used for web enabled apps, but you can also use this tech for desktop, JFrame apps. Contact your RSI Sales Rep for more info if you want to evaluate ION. In the meantime, I will try and get the Callable/JNI example out on our IDL User Contrib site by weeks end. Stay tuned...

-Paul
