---

I was making a code that calls a function, compiled and apparently working well in other situations, and I got an error which says

```
% Variable is undefined: <No name>.
```

```
% Execution halted at:
```

Well what could be this variable that doesn't have a name? It's a little bit surprising for me. And it says that execution was halted at .., but if I wouldn't look at the editor I wouldn't realize that it was producing an error since in the run everything goes well. Can anyone have an idea what can possibly be? I made an HELP for all variables involved with the function and they are all ok.

Another question is related with .SAV files. I know that it may seem a non-sense thing but I would like to know if I can make a .SAV file with arguments, like a routine or a function. I would like to, eventually, execute one of my applications from the operating system having a file as an argument

Thanks,

Nuno.
