Remember that the clipboard has both bitmap and vector modes. The bitmap mode captures the contents of the scene exactly as you would see it on the screen. You can also do pretty much the same thing by getting the data out of the grBuffer and grWindow objects.

Yes, vector output in 6.1 is quite a bit better, but we still need to understand that vector output cannot possibly recreate all the graphical features that you might use on the display. Vector output systems (e.g., PostScript, Windows metafiles) are not really "3D" in any way, while Object Gaphics obviously is a 3D system. It's difficult to map a system with high capabilities onto ones with lesser capabilities. For example, vector systems do not have depth buffers. IDL does a crude depth sort in vector output to approximate the effect of a depth buffer, but it won't sort things out completely. Similar restrictions apply for things like alpha blending.

One of the main motivations for Object Graphics vector output was to reduce the size of the graphics output. In bitmap mode, even a simple plot with a few dozen lines and some text would require several MB of space, depending on the dimensions of the drawable, which seems silly when there is so little data actually in the plot. With vector output, the same data can be represented with a few dozen line plot commands and some text strings, which adds up to a PostScript file of 1K or so in length So vector output can be a big win when working with plots, charts, and other visualizations that are more "2D" than "3D" and don't use a lot of advanced rendering features. Bitmap output is better when you need to preserve all those "3D" qualities.
