
Subject: Can I have multiple threads in IDL?

We're currently running a very large computational program on a multiprocessor machine. When the FFT portion runs, the CPU load on all 8 processors spikes, so IDL is making use of them, life is good.

However, we have another portion of the code that dose a massive nested loop on some arrays, but the operation is carried out on a very small subset of the array and IDL uses only a single processor. It could be easily broken into threads if we were writing in C to allow the OS (Windows Server 2003) to run the threads simultaneously.

We would like to break this processing into multiple threads in IDL so that the task can be run on the other 7 processors in a similar manner. Is there a way to create and run a thread in IDL?

Thanks in advance,
