has anybody used watershed from the idl lib?

When we use watershed, the returned array consists of integers that number the regions that belong together.

0's indicate the boundary of these regions.

so, if from a watershed-segmented image, i want to extract data for a particular segment only, how do i do it?

the fact that a logical segment in an image can contain a number of segment obtained from watershed should be taken into consideration.

if the image can be divided into 6 logical segments, how do i get the data(say, no. of pixels) for segment number 3 that consists of say, 500 small segments (watersheds!) obtained from watershed function.
