
Subject: Problems with plotting with log scaling

If I plot a series of numbers that ranges from let's say 0 to 10e-4 such as in the following IDL command:

```
plot, indgen(10)*.001, /ytype
```

then IDL will scale the value with 8 magnitudes of values from 10e-2 to 10e-16 because I believe that the precision is approaching zero, which is the minimum value.

The problem is that you cannot see anything relevant in a log scaling when the data should be plotted with a minimum at 10e-4 and not 10e-16.

If zero is a valid value is there any way around this besides explicitly forcing the yrange = [10-4,10-2] or min_value = 10e-4 because the plots are generated automatically and all the zero values would be lost.
