Subject: Table Layout?
Posted by hocmin on Tue, 06 Dec 2005 17:44:03 GMT

I'm trying set up a simple two column window where I've got a label in the left column and some corresponding data in the right. The problem is, I can't seem to figure out how you can accomplish this in IDL without alignment problems.

It seems like I can only control over rows OR columns; not both. If I write a loop that generates row widget_base's, for each pair, I can't, for example, align the left one left-justified and the right one right justified. If I write a loop that creates two column bases, my right widget ends up taking more vertical spacing and the elements get out of alignment.

Is there a way to maintain some sort of table layout where you can have both rows and columns of equal size? Or is the only way to do that by setting them absolutely via xsize/ysize or scr_xsize/scr_ysize?

Thanks for any help.
