Indeed, this problem had caused me much grief and frustration in the past. I posted a bug report to ITT that a consequence of PARENT being null is that IDLgrROIGroup::GetCTM() will not return the affine transform with respect to the root scene. This meant that my code which deals with converting mouse clicks to atom coordinates has a special case for IDLgrROIGroup (and IDLgrColorbar). The same code must now also detect IDL 6.3 or above to account for the new behaviour.

So, yes! I'm definately getting different behaviour in IDL 6.3. The curious thing is that the fix was applied *\*after\** IDL 6.3 Beta and isn't documented anywhere I could see. Am I playing with fire here?
