
Subject: failed matrix inversion returns input-- interesting

Can someone explain this behavior?

```
IDL> testm=[[0,0,0,0],[0,1,0,0],[0,0,1,0],[0,0,0,1]]
IDL> testmi=invert(testm,status)
IDL> print,status; 0=success, 1=fail, 2=pivot used
      1
IDL> print,testmi
      0.00000      0.00000      0.00000      0.00000
      0.00000      1.00000      0.00000      0.00000
      0.00000      0.00000      1.00000      0.00000
      0.00000      0.00000      0.00000      1.00000
```

Is there any reason in creation why IDL simply copies the input into the output if it cannot do the inversion? That seems, well, malevolent, unless I'm missing something.
