I have to write a widget/function in idl-envi.
This widget have an "Insert Point" button that collects X,Y coordinates
and some other information related such digital number (color - integer
from 0 to 254), a label (string). Then, points collected must be saved
in ascii file format, in a certain format I know.

How do you suggest to do this? I saw something about .evf file that
store array data format, is this correct? In such conditions, I'll have
to write a evf2ascii function.
Thank you.
