
Subject: IDL -> X-terminal -> Windows using Xwin32, "backing store"?

Because of memory and because it's better, I now do most of my IDL work on a Linux machine (IDL6.2, at this writing). I access this machine, which I have never physically seen, from my Windows box using Xwin32. When I draw a graphics window, it shows symptoms just like the "backing store" problems in the manual: that is, any part of the graphics window that is not "on top" is blank.

I have tried the solutions in the IDL manual for this problem, so I suspect this is an Xwin32 problem rather than an IDL problem, and therefore inappropriate to this group :). But I also suspect I am not the only person reading this group who uses this setup, and you guys are just so darn _helpful_!

Any ideas?
