When using a slider on an app I'm developing I noticed that, once the slider is selected by clicking or dragging it, the arrow keys on my keyboard are also active for moving it. The UP/DOWN keys move the slider one unit at a time.

This is a freebie from idl, I didn't do anything (that I know of!) to make this active. And I had already programmed in ONE\_UP and ONE\_DOWN buttons next to the slider before I noticed this :-). I haven't seen it mentioned in the documentation anywhere.

I don't know how it will behave when you're working near or below the pixel resolution limit. I'm working just with linux/X11/MOTIF so I don't know if it works on other platforms.

But check and see if it's useful for you.

Richard
