Hi everyone,
I am trying to format some plots to look nice for a presentation and I
am having trouble with my tick labels on the x axis. Each label is a
variable name and there are 20 of them, so just printing them under
the axis makes them all run together and thus illegible. Is there
some way after setting the xtickname to an array of variable names to
then rotate each name so that it can sit at maybe a 45 degree angle or
perpendicular to the axis?

Thanks,
Melanie
