
Subject: clustering- yet again

Hi All,

The clustering saga never ended!

I have a large dataset with 5 visibly distinct clusters. Based on advice from y'all, I tried `standardize()` and it worked to some extent. It finds 4 clusters. I have a good idea about my input variables- included the `variable_wts` option and tried, yet with no success.

This is the number of samples it returns in each cluster:

```
IDL> print, clust_num
      6.00000
     28903.0
     25205.0
     37694.0
     42458.0
```

It put only 6 samples into cluster 0, whereas actually I have samples in the range 25000 or so. The remaining samples have been put into cluster 4 (and I can visually see that 0 and 4 are NOT close).

Any ideas on this?

My dataset is very huge to post here, but if anyone is willing to help, I can mail it.

Sincerely,
Nivedita
