I need to display two or more Sun raster greyscale images simultaneously on the screen using IDL (not a Widgets based application). If the images have different intensity ranges, IDL can be made to use the color map of only one of the images. This results in the distortion of all other images. Is there some way around this problem?

A possible solution is to have a different color map used in each window. Another is to compute a color map that best approximates the combined color map of the images to be displayed. Does someone have an implementation of such a solution?

I don't read this group regularly. Please respond by e-mail.
Thank you.
