Hi all,

I wrote a script in IDL which reads multiple images and outputs an
image according to some conditions i specified.
The code works, seemingly with no errors and outputs the required
image. However, when i display the image in ENVI, the output image
looks like a series of tiles/bands as if the values are grouped line-
by-line. The statistics are right, but the display looks really weird.

I had read something about how IDL stores images but i can't quite
find the keywords to search for it.
Does this have to do with any machine settings or is it a setting
within IDL itself ? Any ideas ?

I can attach a graphic if it helps.

Thanks in advance,
Ram
