Subject: The problem about the '.RESET_SESSION' command
Posted by duxiyu@gmail.com on Fri, 27 Jun 2008 03:13:44 GMT

In IDL help, the introduction about this command is below:

"The .RESET_SESSION command resets much of the state of an IDL session
without requiring the user to exit and restart the IDL session."

But I find that there are some different points between the IDL
session after .RESET_SESSION and the restarted one.

If I change the work directory in the session, the .RESET_SESSION
command cannot set the work directory to the default path.

In a restarted session, the current state of the decomposed flag is 1.
I set it to 0 by using 'device, decomposed=0'.
And then run '.reset_session', the current state of the decomposed
flag is still 0 which is different from the restarted session.

Is there a command which can get the same session as a restarted one?

Best regards,
Du Jian
