Hmm...I think for this purpose, your idea sounds like a good workaround.

Thank you. :)

However, I am really curious about the way IDL process instruction from stdin:

why didn't IDL try to stop at all?

The reason I started this in bash is because all my other drivers/scripts related to the simulation is written in bash script. It will be (mentally) satisfying to have everything I created to work in the same environment. I guess having them working in the same environment also makes the usage/maintenance somewhat easier.
