Hi people,

I've a question with the skip_lun function.

Looks the following example:

I've a .dat file that contains a BYTARR(180,240,24) and I want to read a 180x240 matrix on the 7th position ([*,*,7])

I tried something like that:

```
openr, un$lun, file, /get_lun  
skip_lun, un$lun, (180.*240.*7)  
data=bytarr(180,240)  
readu, un$lun, data
```

Now I verify the reading.....

```
point_lun, un$lun, 0  
all_data=bytarr(180,240,24)  
readu, un$lun, all_data  
  
print, total(abs(all_data[*,*,7]-data))  
IDL> 6.71223e+06
```

The result is so different and I don't know why.

Any suggestions? Does anybody knows how is the information saved in a DAT file.

Thanks,

B.
