Is there any function to return the current procedure/function name
only not all?

There is one function "ROUTINE_INFO" which provide information about
all currently-compiled procedures and functions. But, I want to get
the name of the procedure/function using a function (say Routine_Name)
by calling in the same routine. e.g.

Pro test_plot

```
plot,findgen(200)
;
print, Routine_Name()
end
```

The print function should return 'test_plot'.
