Both IDL 6.4 and 7.1 are installed and licensed on a WinXP64 workstation, through the same node-locked license file. Each time that 7.1 is launched, I get a flexlm error message related to "unsupported IDL_dicomex_rw" feature . This message does not come when launching 6.4. Why ?

This behavior is annoying but not fatal, since I do not intend to use this package anyway, and that everything goes ok afterwards in my IDL session.

However, because flexlm does not accept TSE remote connection, I also defined a list of licensing servers by using LM_LICENSE_FILE variable (e.g. "license.dat;remote_license_server;etc..."). Unfortunately, when I am using 7.1, the local license file then get systematically bypassed, even in case of local connection, likely because of the previous "error". Is it a way to avoid that ?
