Hi,

Does anyone know if it is possible to call a fortran function returning an allocated array as is now permitted under fortran 2003?

Specifically, I want to write a library of utilities that can be used by both IDL and fortran to include things such as linspace(a,b,n) to create an array from a to b with n elements. This is easy in both languages of course but I would like to just write the guts of such routines in fortran and call them from a number of languages including IDL.

Regards, Cliff
