Hello all,

I'm running an image conversion procedure, vcr2fits.pro, which
requires two arguments, the image name and the name of the .fits file
that will be created. Due to the large number of images that need to
be converted, I'd like to be able to run it in batches, and have
created lists of file names and output names (rather unimaginatively
named input.list and output.list, respectively). This is probably a
newbie question, but what's the best way to read these lists into IDL
so vcr2fits can process them? With IRAF, for example, this is done by
entering '@input.list' and '@output.list' into the input and output
parameters- I am hoping that an equivalent exists for IDL.

Suggestions?
