Hmmm... not exactly. In the sense that for any point in either list, it is matched to the closest point within the search radius which is not matched to a closer point. So, for example, if my matching radius is 1.5, and my 2 lists are:

1,1 1,2 3,5 6,6
and
1,2.1 0,1.5 5,6 2,2

Then, the optimal match would be to match 2_1 with 1_2, 2_2 with 1_1 (even though 2_2 is closer to 1_2 than 1_1, 1_2 is closer to 2_1), 2_3 with 1_4, and neither 1_3 or 2_4 are matched because they do not have an unmatched star w/in the search radius. In match_2d and srcor, 2_2 wouldn't be matched with anything, because the first pass would match 2_2 with 1_2, but 2_1 would have priority (because it is closer to 1_2) and 2_2 would become unmatched.
